engine of a class such as would be commonly used. Assuming that an engine of thirty or forty indicated horse-power could be made to work at 4lb. of coal per indicated horse-power per hour each, allowing, say 15 per cent. extra for friction, the amount of coal per annum per break horse-power would be nearly $15\frac{1}{2}$ tons.

This result is hardly likely to be obtained with the average engines and boilers met with in the

This result is hardly likely to be obtained with the average engines and boilers met with in the mining districts; as, even with the best makers' engines it is only by using first-class coal, experienced engine-drivers, and working under most favourable conditions for a short time, that the

economical results claimed by them is arrived at.

Those who are most interested in the scheme can form the best opinion, by comparing figures here given with their monthly coal-bills, remembering that the power given out by the electric motors is effective, not nominal or indicated horse-power, and that it includes cost of motors.

The result of such comparisons would be, no doubt, that they will find that steam-power costs

them nearly three times the amount.

The number of motors allowed for in the two estimates is five and seven respectively. Fewer motors, but of larger power, would be employed if the plant was contained in one large battery-house.

Estimated Cost of Plant, and Annual Working-expenses, to deliver 165 Brake Horse-power at Kuaotunu: Power electrically transmitted from Gumtown on the Waiwawa River.
